ABSTRACT

Cloud computing provides the flexible and on-demand business environment based on the resource sharing phenomena to make the service easily available for public utility. Moreover in recent years, workflow scheduling has been one of the prominent cloud computing application; workflow comprises repeated business activity pattern which needs to execute in accordance with sequential checklist. Moreover workflow scheduling requires efficient QoS such as energy consumption, task execution time are important parameter; in past several researcher focused on achieving better performance, however main drawback of these model lies with their efficiency. Hence, in this research we develop an efficient workflow mechanism named EAMM (Energy Aware Makes pan Minimization) to achieve the better performance in workflow scheduling. At first EAMM mechanism designs the problem of processing delay and execution time as a joint problem and solves through the same algorithm. Further this research work focuses on minimizing the make span and energy consumption in VM scheduling. Moreover this is achieved through reducing the execution time on given local processor through designed algorithm. Further EAMM is evaluated by considering the dataset of scientific workflow based Montage and through the comparative analysis it is observed that EAMM simply outperforms the existing model in terms of total execution time and energy consumption.

Keywords: Energy Consumption, Makes pan, task execution, EAMM

1. INTRODUCTION

Cloud computing is an emerging technology which makes use of internet and remote server for providing the services to users; cloud computing is considered as the novel paradigm where the business process and storage[1] which was applicable only for large organizations, can now easily accessed by the smaller companies and individuals as well. Moreover, cloud computing possess various features such as on demand self-service, elasticity, pooling and broad network access; further self-service provides users to pay only for the amount of resource used and time period. Moreover resource pooling indicates unlimited resource availability for customers and various customers can adopt various service in accordance with their demand; elasticity is an added advantage to scale up and scale down resources as per requirement. Virtualization is one of the primary idea of cloud computing that allows various VMs to reside into the single machine [2]-[5].

Moreover users use various VM instances to launch their application and later VM execute the task driven by user. Workflow comprises the repeatable business pattern activities, it is explained as the series of group, an organization, staff or operations represented in DAG (Directed Acyclic Graph)[6]. Here each graph node depicts the process or task and further edges indicates the task dependency. Moreover executing the heavy workflows results in uncertainty error, hence workflows possesses a huge challenge as sometimes hundred tasks needs to be executed in such a way that time and cost has to be managed. Moreover workflows execution are carried out in parts; it starts with submitting an application, making required input file accessible then data transfer and so on. Further there are other constraint which effects the workflow performance such as VMs failure, data transfer. Scheduling a workflow as mentioned is one of the most important and demanding tasks in cloud computing. It is an effortful task and is the primary step of execution of an application [7]. It is the deciding factor of performance of an application. Scheduling basically is a mapping of various workflow tasks on different VMs of various performance factors so as to achieve QoS of users [8]. A workflow is a representation of various independent business tasks which are combined together and are contained in a flow using dependencies, which are a vital part of scheduling. However, workflow scheduling is an NP-hard problem in cloud computing which makes an optimal solution difficult to achieve [9]. Although there can be numerous objectives of users, the most common of them is time and cost. Since there can be numerous requirements (task) of the user with numerous cloud resources, scheduling is done so as to achieve the users' objectives of cost and time by proper allocation of tasks to resources [10].

There has been several method for makes pan minimization, one of the method is known as DFS (Dynamic Frequency scaling) which achieves the makes pan optimization and energy efficient scheduling through scaling down frequency and voltage when given tasks are running. Moreover there are various mainstream manufacturers such as AMD, ARM and Intel which adopts the DVFS technology. Hence considering the importance of DVFS mechanism several important research [11]-[19] included the DVFS mechanism for better performance.

1.1 Motivation and contribution of this research work

In IaaS (Infrastructure as a cloud), users utilize the computing service based on their requirement and pay per use model, further it provides the scalable resources to execute the real world application faster in case of application such as genetic science, earthquake analysis and astronomy. Moreover workflow is general model to describe the scientific application where task set creates forms link among the nodes; further IaaS cloud uses the higher resources which requires high amount of energy and it takes time to execute the task. Moreover the task execution time also known as the makes pan is one of the key factor considering the sensitivity of the workflow application. Task execution time is one factor and another factor is energy consumption. As the energy consumption becomes more then it causes to be more costly and also effects the data center. Hence In this research work we address the problem of makes pan minimization and energy consumption. Further contribution of this research work can be highlighted through below points.

- In this research work, we have developed a mechanism named EAMM (Energy Aware makes pan minimization) mechanism to minimize makes pan and energy consumption.
- We develop mathematical formulation of EAMM and EAMM based algorithm to achieve the objective.
- Review analysis of existing efficient workflow model and highlight the drawbacks of existing workflow.
- In order to achieve the objective of makes pan minimization at first we consider the problem of minimizing the execution time and weight offloading. Later we minimize the ratio of performance and offline algorithm,.
- EAMM is evaluated by considering the standard scientific workflow montage and its variant which is in a form of DAX file. Further evaluation is carried out through comparative analysis.
- Comparative analysis shows that our model excels in terms of energy consumption and task execution time.

Workflow execution is one of the important and vast area of research, hence in order to design an efficient workflow model, we need to perform the extensive survey of existing model. In the next section we perform the extensive review of existing workflow model.

2 Literature Survey

In this section a brief literature is discussed to reduce the drawbacks such as energy consumption, ineffective resource allocation and performance degradation presented by different researchers in the field of for cloud computing environment. [20] developed QoS aware workflow scheduling technique, here algorithm identifies a workflow PCP and assigns that PCP to available resources that tends to reduce the resource cost to meet the deadlines. Further the algorithm implies a recursive approach for the previously scheduled task developed at PCP. Moreover this algorithm also satisfies the general properties of cloud model such as flexibility and elasticity. Moreover [21]

developed cost aware workflow scheduling algorithm for reduction in makes pan and workflow cost; it classifies the resources based on the different QoS workflow metrics. Moreover this algorithm was well intended to rule based mechanism for choosing the best fit workflows resources, this tries to optimize the workflow make span and meet the QoS constraint. [22] developed a partition based strategy to solve the workflow scheduling problem, here algorithm develops the sub-workflow through the main workflow though partition strategy. This also further minimizes the task communication overhead and optimizes the execution time this strategy distributes the task on given optimal instances through maintaining the suitable scheduling strategy. [30] developed an efficient workflow scheduling mechanism through optimizing execution time, here this algorithm has two particular objectives i.e. meeting the budget constraint and minimizing the makes pan. Here at first the strategy select an optimal resource set which minimizes the total cost which meets the budget constraint later the algorithm tends to schedule the task in such optimal way that it suits the resource which is based on the heuristic approach. [23] designed dynamic workflow strategy application; in here algorithm computes the workflow execution and maintains the optimal scheduling strategy through dual stochastic function such as characteristics and distribution functions. Moreover the primary intention here was to increase the estimating accuracy and workflow makes pan to increase the algorithm performance. Moreover algorithm applies different minimization to increase the algorithm performance and workflow scheduling strategy. [24] developed a dynamic workflow which was cost efficient and meets the deadline, this method considered the dynamic resource provisioning in cloud data center through mean clustering and subset sum problem. [25] developed a resource efficient workflow scheduling to meet the objective of makes pan minimization and resource utilization, the author mainly focused on the finding the optimal workflow scheduling such as server reliability maximization, reduction in total execution time and minimizing the makes pan. [26] Developed a keen point driven algorithm to match up the objective, author focused on deadline aware and cost efficient workflow scheduling to reduce the cost and makes pan to meet the user defined constraint. Similarly [27] developed deadline aware cost effective workflow scheduling to minimize makes pan, here the algorithm tries to maintain the optimal scheduling plan for given workflows assigns the given task to the resources on given rank on rank-based policy. Other method like [28] and [29] focused on achieving the better efficiency model and achieve better performance, however it was mainly based on the cost and it comprises with scheduling performance.

In above literatures, various problems such as optimization problem, high computational complexity, energy consumption and ineffective resource utilization etc. exists which can degrade their performance and hence difficult to introduce in real time scenarios. Therefore, an effective resource scheduling technique is needed to maintain a balancing between energy consumption and high performance based on DVFS due to its various energy saving capabilities for a cloud computing environment. Therefore, we have presented a EAMM technique for cloud computing devices which efficiently decreases energy consumption as well as executes operations in very less time through makespan minimization.

This particular research work is organized like any other research work, first section focus on the parallel computation and the need for parallel computation and steps related to makes pan optimization. Further the sub section of first section highlight the research contribution. Second section discuss the various existing methodologies used for the performance enhancement and their drawbacks are highlighted. Third section presents the EAMM mechanism along with the Makes pan optimization model, resource allocation and task scheduling mechanism. Similarly fourth section presents the evaluation of EAMM mechanism.

3 Proposed methodology

In this section we develop and design a particular mechanism named EAMM (Energy Aware Makes pan minimization) mechanism to reduce the makes pan and improve the energy efficiency of the overall model. Moreover this is achieved through considering the delay in task processing; in this research work we consider the makes pan minimization problem. In general a scheduler minimizes the makes pan through unloading task, however it affects cost, considering these scenario we design EAMM mechanism and the problem

3.1 System model and preliminaries

Let's consider any hybrid cloud model where the device access to m identical parallel process denoted by $j \in \mathcal{M} = \{1, \dots, n\}$. Moreover initially we consider that remote cloud as the single powerful processor referred as processor 0. Later we extend our work to multiple processor. Initially we assume that all task are available at time 0.

Let's consider non-pre-emptible and independent tasks n that are available to given scheduler at time is zero; let's consider $\mathcal{U} = \{1, \dots, n\}$ be task indices with processing time for task is unknown and denoted as v_k . Moreover main intention here is to optimize the makes pan of scheduled task on the given processor; in here we consider the offloading cost and makes pan together through weighted sum. Let \mathcal{T} be the set of possible schedule and t be the schedule, further t decides offloading of task on processor; let $\mathcal{U}_j(t)$ be the task scheduling set on processor $j \in \mathcal{M} \cup \{0\}$ under given schedule t . Consider $\mathcal{D}_j(t)$ as the total time taken to complete the assigned to processor and it is formulated through the below equation.

$$\mathcal{D}_j(t) = \sum_{k \in \mathcal{U}_j(t)} v_k, \forall j \in \mathcal{M} \quad (1)$$

$$\mathcal{D}_0(t) = \sum_{k \in \mathcal{U}_0(t)} \Xi_k \quad (2)$$

Further as Ξ_k is unknown, cost is given as

$$C(t) = \sum_{j \in \mathcal{T}_0(s)} \widehat{c}_k \quad (3)$$

Moreover total cost of schedule s is given through below equation

$$\aleph(t) \triangleq \max_{j \in \mathcal{M} \cup \{0\}} \{D_j(t)\} + x\gamma(t) \quad (4)$$

In the above equation w indicates weight parameter which allows to tune importance between cost and makes pan, further cost minimization can be given as:

$$\underset{t \in \mathcal{T}}{\text{minimize}} \aleph(t) \quad (5)$$

3.2 Intermediate framework

In here we design an intermediate framework where processing time \mathcal{V}_k is unknown and costs are $\widehat{b}_k, \forall k$; in order to develop this intermediate framework we consider Q as a problem instance of Q_{sum} . Further $t(Q)$ is schedule of online algorithm and $\bar{t}^*(Q)$ is schedule of an optimal algorithm. Further the interactive framework is given as:

$$\max_{\forall Q} \aleph(t(Q)) (\aleph(\bar{t}^*(Q)))^{-1} \leq \delta \quad (6)$$

In here θ is tight for algorithm such that it satisfies the below equation.

$$\aleph(t(Q)) = \delta \aleph(\bar{t}^*(Q)) \quad (7)$$

3.3 Problem definition

In this section we define the problem which is to reduce the makes pan on given $m + 1$ processor p_{max} as the cost of off-loading

$$\underset{t \in \mathcal{T}}{\text{minimize}} D_{\text{max}}(t) \quad (8)$$

In the above equation $D_{\text{max}}(t)$ is formulated as

$$D_{\text{max}}(t) \triangleq \max \{ \max_{i \in \mathcal{M} \cup \{0\}} D_i(t), xU(t) \} \quad (9)$$

Moreover q_{max} and D_{max}^* indicates objective and further optimal schedule is denoted through t^* ; further if $x=0$ then q_{max} is minimal on $n + 1$ processor.

3.3.1 Relation between q_{sum} and q_{max}

Let s' be considered as computed schedule for solving the q_{max} , further inequalities are formulated as:

$$\aleph(t') = \max_{j \in \mathcal{M} \cup \{0\}} \{D_j(t')\} + xC(t') \quad (10)$$

$$= 2\delta \aleph(\bar{t}^*)$$

Moreover in the above equation we observe that q_{max} and q_{sum} requires similar solution, hence we develop mechanism for q_{max} . Moreover this is achieved through establishing the lower bound for C_{max}^*

Let D_j^* denotes completion time and U_j^* indicates task scheduled on given processor j under optimal schedule U_j^* . optimal equation is formulated as:

$$\mathcal{D}_j^* = \sum_{k \in \mathcal{U}_j^*} \forall k \in \mathcal{M}, v_k \quad (11)$$

$$\mathcal{D}_0^* = \sum_{k \in \mathcal{U}_0^*} \Xi v_k \quad (12)$$

$$\mathcal{D}_{\max}^* \geq \sum_{k \in \mathcal{U}_j^*} \forall j \in \mathcal{M}, v_k \quad (12)$$

$$\mathcal{D}_{\max}^* \geq \sum_{k \in \mathcal{U}_j^*} \Xi v_k \quad (13)$$

Further substituting \mathcal{D}_{\max}^* in equation (12) and (13), we achieve:

$$\sum_{k=1} v_k \leq \left(n + \frac{1}{\Xi} \right) \mathcal{D}_{\max}^* \quad (14)$$

Further, \mathcal{D}_{\max}^* be the optimal objective, t' be the optimal schedule for scheduling task \mathcal{U} with earlier assumption regarding the processing time. \mathcal{D}_j^* be the schedule length, $\mathcal{U}'_0 \subseteq \mathcal{U}'$ be the task offloaded then we have further equation

$$\sum_{k \in \mathcal{U}_0} b_k = \frac{1}{\kappa} \sum_{j=1}^n \mathcal{D}_j^* + \sum_{k \in \mathcal{U}'_0} b_k \quad (15)$$

Further we use $\mathcal{D}_{\max}^* \geq \mathcal{D}_j^*$, $\forall j \in \mathcal{M} \cup \{0\}$ and $\mathcal{D}_{\max}^* \geq \sum_{k \in \mathcal{U}'_0} b_k$ and obtain

$$\sum_{k \in \mathcal{U}'} b_k \leq \left(1 + \frac{n}{\kappa} \right) \mathcal{D}_{\max}^* \quad (16)$$

3.4 EAMM Algorithm

EAMM algorithm forms a task lost in accordance with their offloading cost b_1 , further task in given list is scheduled one after the other on given processor \mathcal{Y} . Moreover the proposed EAMM algorithm have not idea about the processing time of given task k on processor \mathcal{M} ; hence κb_k is used for computing the processing time of task k which is scheduled on processor and further task is terminated if it exceeds more than estimated time. Moreover here we have considered $\kappa \geq 1$ in such a way that task does not get terminated until it is processed.

Moreover after scheduling task and performing iteration; tasks that are terminated are sorted again and task lists are arranged in ascending order of b_k ; in next iteration task lists are scheduled where task are not terminated except last .

Step1:	initialize $m = 1, \mathcal{U}^{(m)} = 1$
Step2:	While $m \leq 2$ do
Step3:	$k_1 = 1, k_0 = \mathcal{U}^{(m)} + 1$
Step4:	Sort $\mathcal{U}^{(m)}$ in ascending order of given b_k
Step5:	Re – indexing task in order of $b_1 \leq b_2 \leq \dots \leq b_{ \mathcal{U}^{(m)} }$
Step6:	Starting of task k_1 on given processor \mathcal{Y}
Step7:	for $\ell = 1$ to $\min\{n, \mathcal{U}^{(m)} \}$ do
Step8:	$k_0 = k_0 - 1$
Step9:	processing of task k_0 on given processor ℓ
Step10:	If $m = 1$ Then Terminate task k_0 if execution of task exceeds κb_{k_0} and include in \mathcal{U}^2 End if End for loop
Step11:	While $\mathcal{U}^{(m)} \neq 0$ do
Step12:	Waiting for event \mathcal{F} occurrence
Step13:	If $\mathcal{F} =$ a task \hat{k} (cancelled or completed on processor $\hat{j} \in \mathcal{M}$)
Step14:	Cancel the task \hat{k} if it is scheduled
Step15:	$\mathcal{U}^{(m)} = \mathcal{U}^{(m)} \setminus \{\hat{k}\}$ $k_0 = k_0 - 1$
Step16:	If ($k_0 > k_1$) then Task scheduling on processor \hat{i} End of if condition
Step17:	If ($m = 1$) Task cancellation of k_0 if the execution time exceeds κb_{k_0} Include task into $\mathcal{U}^{(2)}$ End of if statement
Step18:	Else if $\mathcal{F} =$ task k_1 which is completed on processor then Cancel task k_1 if particular task is scheduled on processor
Step19:	$\mathcal{U}^{(m)} = \mathcal{U}^{(m)} \setminus \{\overline{\mathcal{U}^{(m)}}\}$ $k_0 = k_0 - 1$
Step20:	IF(task k_1 is not completed) then Schedule task k_1 on processor
Step21:	End of if statement(step20)
Step22:	End of if stament(step13)
Step23:	End while (11)

Step24:	$m = m + 1$
Step25:	End while (step2)

3.4.1 Minimizing the ratio.

In this section we tend to minimize the ratio of performance and offline algorithms., here considering the set of task $\mathcal{U}^{(m)}$ in given m iteration. Schedule length is denoted by $\mathcal{D}_{\max}^{(m)}(t^{\text{EAMM}})$, t_m be the further schedule. The main advantage of proposed algorithm is that it can optimize the competitive ratio through proper κ . In here, at first we use higher value which allows task to run for longer period. Later we use smaller value of κ for aggressive cancellation. Further considering the optimization problem, here we tend to minimize the upper bound of ratio and minimization problem is given as:

$$\begin{aligned} & \text{minimize} & (17) \\ & \kappa \geq 1 \end{aligned}$$

Further solution of above equations are given as:

$$\kappa = \begin{cases} 1 & n = 1 \\ 0.5(n)^{1/2} & n \geq 2 \end{cases} \quad (18)$$

Further using the above equation of \mathcal{D}_{\max} we get

$$(t^{\text{EAMM}})(\mathcal{D}_{\max}^*)^{-1}\mathcal{D}_{\max} \leq \begin{cases} 4 & n = 1 \\ 1 + 2(2n)^{1/2} & n \geq 2 \end{cases} \quad (19)$$

4 PERFORMANCE EVALUATION

Now a days, the request of CC (cloud computing) resources has highly emerged in real-time due to its vibrant uses, flexibility, cost effective and easily accessible at anywhere anytime through internet. Multimedia-signal-processing method is well-known technique that can be utilize in these CC-devices. Therefore, the performance of these computing devices must be superior due to the extensive demand of these computing devices in day-to-day life. However, high energy consumption in these computing devices can disturb their performance; further makes pan is an important constraints, hence to optimize these objectives, we have introduced a EAMM

For heterogeneous computing devices which efficiently reduces energy consumption as well as provide superior performance. The run-time can be evaluated considering various jobs as 25, 50, 100, and 1000. Graphical representation of our outcomes is also presented considering execution-time, number of tasks and energy consumption. The run-time and total power consumed can be evaluated using different parameters in table 1 which is demonstrated in the following section. Our proposed model EAMM is tested on Montage scientific dataset; The Montage application is created by NASA/IPAC stitches together multiple input images to create custom mosaics of the sky [30]. Figure 1 shows the montage scientific workflow. Moreover proposed EAMM is evaluated considering 64-bit with operating system of windows 10 with 16 GB RAM and loaded

with I5 processor; further the model 3.20 GHz CPU and the model is evaluated using the programming language using java and neon .3 editor.

Moreover EAMM is evaluated through varying the number of virtual machine as 20, 40 and 60, these varied results are compared with the existing model by considering the for eminent parameter i.e. total execution time, power sum, power average, average power and energy consumption. In here table 2 and table 3 presents the comparison of existing model with the proposed EAMM model by varying the virtual machine as 20, 40 and 60.

Table 1 Comparison of existing model and EAMM on virtual machine 20

Number of VM	ES			EAMM		
	20	40	60	20	40	60
Total Execution Time (s)	6359.41 sec	12380.99 sec	24712.57 sec	3030.25 sec	2953.86	5898.82 sec
Energy Consumption (Wh)	3495.42	7028.52	3495.42	416.88	1330.92	894.063

Table 2 comparison of existing and EAMM on virtual machine 40

4.1.1.1 Montage_25

In this sub-section we evaluate the EAMM methodology on montage_25 node dax by varying the number of VM; further comparison is given based on two parameter i.e. total time taken and energy consumption as both are very important factor. In here below figure i.e. figure 2 and figure 3 shows comparison on total simulation time and Energy Consumption. In figure 2, X-Axis indicates number of VM, y- axis indicates time taken in seconds. Moreover considering the dynamic environment of cloud the less time it takes the better and efficient the model; in here for 20 VM existing model takes 6310.87 seconds whereas EAMM mechanism takes only 2883.65 seconds. For 40 VM time taken to complete the task is 8965.28 and for proposed time taken is 2883.65. Similarly for 60 VM existing model takes 6923.13 sec and EAMM takes 2883.65 sec. Further for 20 VM, 40VM and 60 VM energy consumption for existing mechanism is 3491.37, 5423.21 and 4079. 23 respectively whereas EAMM mechanism takes 1280.94, 1287.94 and 1287.94 respectively.

Table 3 tabular comparison of existing model and EAMM on montage_25

Number of VM	ES			EAMM		
	20	40	60	20	40	60
Total Execution Time (s)	6310.87 sec	8965.28 sec	24712.57 sec	2883.65 sec	2883.65	2883.65sec
Energy Consumption (Wh)	3491.37	5423.21	4079.23	1280.94	1287.94	1287.94

Figure 3 Energy Efficient comparison on maontage 25

4.1.1.2 Montage_50

Further evaluation is carried out on Montage _50; in here for 20 VM, simulation time taken is 9272.74, 8965.28 and 6923.28 respectively whereas proposed mechanism takes 2984.39 sec in case of all VM. Hence it is observed that proposed model takes comparatively less time than the existing mechanism. Similarly energy consumption for VM 20, 40 and 60 are 5649.82, 5423.21 and 4079.23 respectively, however proposed mechanism consumes 1340.94, 1456.94 and 1480.94 respectively.

Table 4 tabular comparison of existing model and EAMM on montage_50

Number of VM	ES			EAMM		
	20	40	60	20	40	60

4.1.1.4 Montage_1000

Table 6 shows the comparison of existing and EAMM mechanism on Montage 1000 node DAX, in here for Montage 1000 through 20, 40 and 60 VM existing model takes 8765.47, 12217.74 and 12737.5 respectively to execute the task whereas EAMM takes 5715.3, 5646.85 and 5646.85 respectively. Further Energy consumed through 20, 40 and 60 are 6313.95, 8501.44 and 8867.34 respectively for existing model, whereas 4196.13, 4171.32 and 4171.32 respectively for EAMM mechanism.

5 CONCLUSION

Workflow scheduling has become one of the important and challenging issues considering the emerging distributed environment; further due to the dynamic environments its essential to satisfy the QoS constraint such as Energy consumption, makes pan. Cloud gets the application in form of workflow that comprises the inter-dependent task set for solving the enterprise or large scale scientific problem. In this research work we focus on minimizing the makespan through monitoring the processing delay. Further EAMM is evaluated considering the important metrics as makes pan and energy consumption; in order to evaluate we consider the scientific workflow

named montage and its various model; further evaluation is considered through comparative analysis with the existing model of makespan and energy consumption and through the comparative analysis it is observed that our model simply outperforms the existing model.

Workflow execution is an extensive research area with various number of constraint and parameter, although EAMM shows the remarkable improvement in terms of task execution time and energy consumption. There are several research area such as power aware which we will be focusing in the next research work and evaluating model by considering the different workflow to prove the better efficiency of model.
